ments, being imner on ons, middle on the next, and outer on the third; but a portion of the imer remains imer throughout.

Diyestice system. 'The salivary glands are 4 mm. long, Hat and simple, hent abruptly outward heyond the middle. tapering slightly and regularly to a bluntly rounded tip.

The malpighian ressels originate in an owal gland or sac, ( 0.45 mm. long and 0.2 mm . broad, a short distance beyond which the under branch is thrown off and immediately afterwarl the two others. The muler branch passes forward in a straight and not a tortuous comse, and is proportionally about as long as in Dumuis; the upper branch extends forward for a distance of 3.75 mm . the lateral to the point where the silk ressels bend, 7 mm . from its origin.

Nercous system. The cephalic lohes are globular. The cords connecting the second and third body-ganglia run together for nearly one-quarter the distance from the scond backward. then diverge considerably, and again converging, enter the third ganglion at a perceptible distance apart; netrly the same is repeated between the first and second ganglia, but
they diverge nearly from their origin; between the first body-ganglion and the suboesophagealganglion the cords are parallel, but separate, and a little parted in the middle. The third ganglion lies in the middle of its segment, the fourth at the anterior edge of its segment, and only 0.75 mm . from the third ; the fifth in the middle of the auterior half of its segment ; the eleventh ganglion is considerably longer than broad, and the pair of posterior, hackwardly directed, diverging nerves is larger than any of the others, and may be looked upon as the continuation of the connecting cords between the other ganglia.

Giandular system. The basal thread of the silk ressels is straight and not tortuons; the basal half of the stouter vessel is flattened; it extends hackward as far as the third abdominal segment and then turns abruptly, with a slight formard curve, to the upper side of the body, where it continnes in a straight line as far, apparently, as the end of the sixth abdominal segment. The length of the initial thread or duct is 3.25 mm . ; of the portion of the ribbon or ressel upon the under surface 4 mm . ; of that upon the upper surface 5.25 mm .
(To be contimued oul $f$. 319.)

## COLOR OF THE LIGHT EMITTED BY INSEC'FS.

## By IIENRY WARU TURNER, ITIIACA, N. Y.

Sume specimens of Pyrophorus nortilucus Linn.. from the West Indies, that were brought to the Academy of natural sciences, at Philadelphia, gave out a rery bright-green light from the two dorsal prothoracic spots, and also from the rentral surface near the base of the abdomen. Cosse (Amn. aml mag, nat.
hist., 1848 , s. 2, v. 1, p. 200) says they give out a rich yellow-green light when flying and a green light when in captivity. Photmris pensyluraical gives out (sometimes at least) a very decided green light, and Photimus pyralis a yellow light from the ventral surface of the two or three last segments of the abdomen.
